

Well that is just perfect. I gave the same document to Chatgpt, Gemini, Codex and Claude code. They were not able to provide the same "Glass" themed image. All the provided images were Flat and not transparent at all. . . Is there something in the document that only you can understand? Why are they not getting the same results?

The document itself is the same for everyone — nothing in it is uniquely readable only by me. The difference comes from **how the visual target is translated into an image-generation prompt**.

What the document actually emphasizes

The specification repeatedly stresses a specific set of visual properties that define “glass”:

- Semi-transparent dark panels (`rgba(..., 0.58)` etc.)

- `backdrop-filter: blur(...)` so the aurora background shows through

- Thin cyan-tinted borders + subtle top-edge white highli

ght

- Soft ambient radial glows (cyan left, orange right) that are only visible *through* and *around* the glass

- Different opacity levels depending on content density (tables more opaque, summary cards more transparent)

- Explicit instruction that the background must stay quiet and the glass must be restrained, not neon or flat

Those are the ingredients of smoked-glass glassmorphism.

Why other models often produced flat results

Most image models (and the systems that write prompts for them) tend to default to:

- Solid dark cards with hard edges

- Flat color blocks

- “Modern dashboard” aesthetics that look clean but opaque

- Overly bright neon or cyberpunk treatments when they try to interpret “glass”

If the prompt does not **aggressively and repeatedly** force the model to render translucency, background bleed-through, blur, and the specific ambient glows, the model falls back to the safer, more common “flat dark UI” look. The CSS values and the repeated warnings about readability vs. effect are easy to under-weight or ignore when turning the document into a short image prompt.

What I did differently

I treated the CSS and the design-direction sections as literal visual instructions and built a prompt that forced those exact properties:

- “semi-transparent dark smoked-glass panels”
- “moderate backdrop blur”
- “thin low-opacity cyan-tinted borders”
- “subtle white top-edge highlights”
- “soft cyan/teal glow left, orange glow right showing through the glass”
- “smoked-glass business command center, restrained, not neon”

That combination of concrete material descriptions + the specific ambient lighting is what produces the transparent/glassy result instead of solid panels.

Bottom line

There is no secret knowledge in the document. The difference is prompt engineering fidelity: how completely the CSS values, the ambient-light description, and the “restrained glass” priority are preserved when the text is turned into an image prompt. Other models can produce the same result if given a sufficiently detailed and insistent prompt that keeps repeating the translucency, blur, and background-glow requirements.
